1 Streams

- Streams are identified within a connection by a numeric value, referred to as the stream ID. A stream ID is a 62-bit integer (0 to $2^{62}-1$) that is unique for all streams on a connection.

Bits	Stream Type
0x0	Client-Initiated, Bidirectional
0x1	Server-Initiated, Bidirectional
0x2	Client-Initiated, Unidirectional
0x3	Server-Initiated, Unidirectional

Table 1: Stream ID Types

2 Variable-Length Integer Encoding

QUIC packets and frames commonly use a variable-length encoding for non-negative integer values. This encoding ensures that smaller integer values need fewer bytes to encode.

The QUIC variable-length integer encoding reserves the two most significant bits of the first byte to encode the base 2 logarithm of the integer encoding length in bytes. The integer value is encoded on the remaining bits, in network byte order.

This means that integers are encoded on 1, 2, 4, or 8 bytes and can encode 6, 14, 30, or 62 bit values respectively. Table 4 summarizes the encoding properties.

2Bit	Length	Usable Bits	Range
00	1	6	0-63
01	2	14	0-16383
10	4	30	0-1073741823
11	8	62	0-4611686018427387903

3.3 Stateless Reset Packet

Figure 6: Stateless Reset Packet

4 Transport Parameter Encoding

Figure 16: Sequence of Transport Parameters

Figure 17: Transport Parameter Encoding

original_connection_id (0x00): The value of the Destination Connection ID field from the first Initial packet sent by the

client. This transport parameter is only sent by a server. This is the same value sent in the "Original Destination Connection ID" field of a Retry packet (see Section 17.2.5). A server MUST include the `original_connection_id` transport parameter if it sent a Retry packet.

`max_idle_timeout (0x01)`: The max idle timeout is a value in milliseconds that is encoded as an integer; see (Section 10.2). Idle timeout is disabled when both endpoints omit `this` transport parameter or specify a value of 0.

`stateless_reset_token (0x02)`: A stateless reset token is used in verifying a stateless reset; see Section 10.4. This parameter is a sequence of 16 bytes. This transport parameter MUST NOT be sent by a client, but MAY be sent by a server. A server that does not send `this` transport parameter cannot use stateless reset (Section 10.4) for the connection ID negotiated during the handshake.

`max_packet_size (0x03)`: The maximum packet size parameter is an integer value that limits the size of packets that the endpoint is willing to receive. This indicates that packets larger than `this` limit will be dropped. The default for `this` parameter is the maximum permitted UDP payload of 65527. Values below 1200 are invalid. This limit only applies to `protected` packets (Section 12.1).

`initial_max_data (0x04)`: The initial maximum data parameter is an integer value that contains the initial value for the maximum amount of data that can be sent on the connection. This is equivalent to sending a `MAX_DATA` (Section 19.9) for the connection immediately after completing the handshake.

`initial_max_stream_data_bidi_local (0x05)`: This parameter is an integer value specifying the initial flow control limit for locally-initiated bidirectional streams. This limit applies to newly created bidirectional streams opened by the endpoint that sends the transport parameter. In client transport parameters, `this` applies to streams with an identifier with the least significant two bits set to 0x0; in server transport parameters, `this` applies to streams with the least significant two bits set to 0x1.

`initial_max_stream_data_bidi_remote (0x06)`: This parameter is an integer value specifying the initial flow control limit for peer-initiated bidirectional streams. This limit applies to newly created bidirectional streams opened by the endpoint that receives the transport parameter. In client transport parameters, `this` applies to streams with an identifier with the least significant two bits set to 0x1; in server transport parameters, `this` applies to streams with the least significant two bits set to 0x0.

`initial_max_stream_data_uni (0x07)`: This parameter is an integer value specifying the initial flow control limit **for** unidirectional streams. This limit applies to newly created unidirectional streams opened by the endpoint that receives the transport parameter. In client transport parameters, **this** applies to streams with an identifier with the least significant two bits set to 0x3; in server transport parameters, **this** applies to streams with the least significant two bits set to 0x2.

`initial_max_streams_bidi (0x08)`: The initial maximum bidirectional streams parameter is an integer value that contains the initial maximum number of bidirectional streams the peer may initiate. If **this** parameter is absent or zero, the peer cannot open bidirectional streams until a MAX_STREAMS frame is sent. Setting **this** parameter is equivalent to sending a MAX_STREAMS (Section 19.11) of the corresponding **type** with the same value.

`initial_max_streams_uni (0x09)`: The initial maximum unidirectional streams parameter is an integer value that contains the initial maximum number of unidirectional streams the peer may initiate. If **this** parameter is absent or zero, the peer cannot open unidirectional streams until a MAX_STREAMS frame is sent. Setting **this** parameter is equivalent to sending a MAX_STREAMS (Section 19.11) of the corresponding **type** with the same value.

`ack_delay_exponent (0x0a)`: The ACK delay exponent is an integer value indicating an exponent used to decode the ACK Delay field in the ACK frame (Section 19.3). If **this** value is absent, a **default** value of 3 is assumed (indicating a multiplier of 8). Values above 20 are invalid.

`max_ack_delay (0x0b)`: The maximum ACK delay is an integer value indicating the maximum amount of time in milliseconds by which the endpoint will delay sending acknowledgments. This value SHOULD include the receivers expected delays in alarms firing. For example, **if** a receiver sets a timer **for** 5ms and alarms commonly fire up to 1ms late, **then** it should send a `max_ack_delay` of 6ms. If **this** value is absent, a **default** of 25 milliseconds is assumed. Values of 2^{14} or greater are invalid.

`disable_active_migration (0x0c)`: The disable active migration transport parameter is included **if** the endpoint does not support active connection migration (Section 9). Peers of an endpoint that sets **this** transport parameter MUST NOT send any packets, including probing packets (Section 9.1), from a local address or port other than that used to perform the handshake. This parameter is a zero-length value.

`preferred_address (0x0d)`: The server's preferred address is used to effect a change in server address at the **end** of the handshake, as

described in Section 9.6. The format of [this](#) transport parameter is shown in Figure 18. This transport parameter is only sent by a server. Servers MAY choose to only send a preferred address of one address family by sending an all-zero address and port (0.0.0.0:0 or ::.0) [for](#) the other family. IP addresses are encoded in network [byte](#) order. The CID Length field contains the length of the Connection ID field.

Figure 18: Preferred Address format

`active_connection_id_limit (0x0e)`: The active connection ID limit is an integer value specifying the maximum number of connection IDs from the peer that an endpoint is willing to store. This value includes the connection ID received during the handshake, that received in the preferred_address transport parameter, and those received in NEW_CONNECTION_ID frames. Unless a zero-length connection ID is being used, the value of the `active_connection_id_limit` parameter MUST be no less than 2. If [this](#) transport parameter is absent, a [default](#) of 2 is assumed. When a zero-length connection ID is being used, the `active_connection_id_limit` parameter MUST NOT be sent.

6 Transport Error Codes

QUIC error codes are 62-bit unsigned integers. This section lists the defined QUIC transport error codes that may be used in a CONNECTION_CLOSE frame. These errors apply to the entire connection.

NO_ERROR (0x0): An endpoint uses [this](#) with CONNECTION_CLOSE to signal that the connection is being closed abruptly in the absence of any error.

INTERNAL_ERROR (0x1): The endpoint encountered an internal error and cannot [continue](#) with the connection.

SERVER_BUSY (0x2): The server is currently busy and does not accept any [new](#) connections.

FLOW_CONTROL_ERROR (0x3): An endpoint received more data than it permitted in its advertised data limits (see Section 4).

STREAM_LIMIT_ERROR (0x4): An endpoint received a frame [for](#) a stream identifier that exceeded its advertised stream limit [for](#) the corresponding stream [type](#).

STREAM_STATE_ERROR (0x5): An endpoint received a frame [for](#) a stream that was not in a state that permitted that frame (see Section 3).

FINAL_SIZE_ERROR (0x6): An endpoint received a STREAM frame containing data that exceeded the previously established `final` size. Or an endpoint received a STREAM frame or a RESET_STREAM frame containing a `final` size that was lower than the size of stream data that was already received. Or an endpoint received a STREAM frame or a RESET_STREAM frame containing a different `final` size to the one already established.

FRAME_ENCODING_ERROR (0x7): An endpoint received a frame that was badly formatted. For instance, a frame of an unknown `type`, or an ACK frame that has more acknowledgment ranges than the remainder of the packet could carry.

TRANSPORT_PARAMETER_ERROR (0x8): An endpoint received transport parameters that were badly formatted, included an invalid value, was absent even though it is mandatory, was present though it is forbidden, or is otherwise in error.

CONNECTION_ID_LIMIT_ERROR (0x9): The number of connection IDs provided by the peer exceeds the advertised `active_connection_id_limit`.

PROTOCOL_VIOLATION (0xA): An endpoint detected an error with protocol compliance that was not covered by more specific error codes.

INVALID_TOKEN (0xB): A server received a Retry Token in a client Initial that is invalid.

CRYPTO_BUFFER_EXCEEDED (0xD): An endpoint has received more data in CRYPTO frames than it can buffer.

CRYPTO_ERROR (0x1XX): The cryptographic handshake failed. A range of 256 values is reserved `for` carrying error codes specific to the cryptographic handshake that is used. Codes `for` errors occurring when TLS is used `for` the crypto handshake are described in Section 4.8 of [QUIC-TLS].

7 QUIC TLS

7.1 Carrying TLS Messages

+-----+-----+-----+			
Packet Type	Encryption Level	PN Space	
+=====+=====+=====+			
Initial	Initial secrets	Initial	
+-----+-----+-----+			
0-RTT Protected	0-RTT	0/1-RTT	

Handshake	Handshake	Handshake
Retry	N/A	N/A
Version Negotiation	N/A	N/A
Short Header	1-RTT	0/1-RTT

Table 1: Encryption Levels by Packet Type

7.2 Header Protection

```

mask = header_protection(hp_key, sample)

pn_length = (packet[0] & 0x03) + 1
if (packet[0] & 0x80) == 0x80:
    # Long header: 4 bits masked
    packet[0] ^= mask[0] & 0x0f
else:
    # Short header: 5 bits masked
    packet[0] ^= mask[0] & 0x1f

# pn_offset is the start of the Packet Number field.
packet[pn_offset:pn_offset+pn_length] ^= mask[1:1+pn_length]

```

Figure 6: Header Protection Pseudocode

Figure 7 shows the **protected** fields of **long** and **short** headers marked with an E. Figure 7 also shows the sampled fields.

```

Long Header:
+---+---+---+---+---+---+
|1|1|T T|E E E E|
+---+---+---+---+---+---+
|                                     Version -> Length Fields ...
+---+---+---+---+---+---+

Short Header:
+---+---+---+---+---+---+
|0|1|S|E E E E E|
+---+---+---+---+---+---+
|                                     Destination Connection ID (0/32..144) ...
+---+---+---+---+---+---+

Common Fields:
+---+---+---+---+---+---+
|E E E E E E E E Packet Number (8/16/24/32) E E E E E E E E...
+---+---+---+---+---+---+
| [Protected Payload (8/16/24)] ...

```

Figure 7: Header Protection and Ciphertext Sample

The sampled ciphertext for a packet with a short header can be determined by the following pseudocode:

```

sample_offset = 1 + len(connection_id) + 4

sample = packet[sample_offset..sample_offset+sample_length]
sample_offset = 7 + len(destination_connection_id) +
                  len(source_connection_id) +
                  len(payload_length) + 4
if packet_type == Initial:
    sample_offset += len(token_length) +
                    len(token)

sample = packet[sample_offset..sample_offset+sample_length]

```

7.3 Retry Packet Integrity

The Retry Integrity Tag is a 128-bit field that is computed as the output of AEAD_AES_128_GCM [AEAD] used with the following inputs:

- * The secret key, K, is 128 bits equal to 0x4d32ecdb2a2133c841e4043df27d4430.
- * The nonce, N, is 96 bits equal to 0x4d1611d05513a552c587d575.
- * The plaintext, P, is empty.
- * The associated data, A, is the contents of the Retry Pseudo-Packet, as illustrated in Figure 8:

The secret key and the nonce are values derived by calling HKDF-Expand-Label using 0x656e61e336ae9417f7f0edd8d78d461e2aa7084aba7a14c1e9f726d55709169a as the secret, with labels being "quic key" and "quic iv" (Section 5.1).

```
